Fine-tuning

- **Training** a **pre-trained model** (like **GPT** models) on your **data**
- **Adjusts** model's **weights** (internal parameters)
- Helps **model** follow your **style** and **improve** accuracy
- Changes **behavior**, not just adds data

How it is done ?

- Start with a **pre-trained model**
- Prepare **dataset** (input → correct output)
- **Model** generates **output** → **compare** with **correct answer**
- Calculate **error** → **adjust weights** slightly
- **Repeat** many times → **model** learns **patterns**

```
{
  "input": "I want my money back",
  "output": "refund"
}
```

Example:

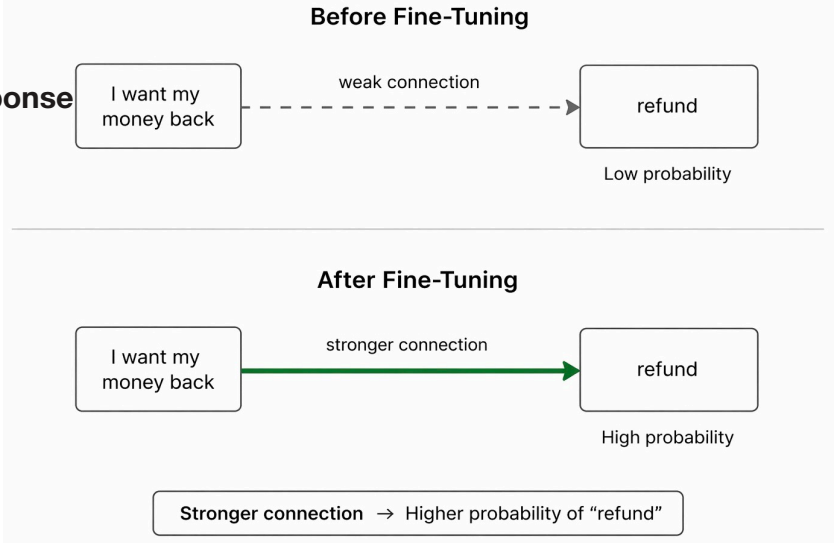

Task: classify support queries

Before:

"I want my money back" → **generic response**

After:

"I want my money back" → "**refund**"

Why ?

- Before: **weak connection** → "money back" ↔ refund
- After: **stronger connection** → **higher probability** of "**refund**"
